Masanori Ishida
Cusp singularities and discrete groups generated by reflections

Abstract. Since GL($r, \mathbb{Z}$) is the automorphism group of the algebraic torus $(\mathbb{C}^\times)^r$, any subgroup $\Gamma$ of GL($r, \mathbb{Z}$) acts on the algebraic torus, and the action may extend to some toric variety including it. For instance, if $\Gamma$ is finite, then it acts on a projective toric variety.

We are interested in such a group $\Gamma$ that the orbit of a point in the lattice $\mathbb{Z}^r$ generates an open convex cone $C$ in $\mathbb{R}^r$ without lattice points on the boundary except at the origin. In such case, some subgroup $\Gamma' \subset \Gamma$ of finite index acts freely on the cone, and it defines a cusp singularity introduced by Tsuchihashi, using toric geometry.

However, not so many groups with this property are known. I will talk on examples for $r = 4$, and will comment on the relation with the works of Vinberg on infinite Coxeter groups.

13:30-14:30

A variant of Shokurov’s criterion of toric surface

Abstract. For a log canonical pair $(X, D)$ of a normal projective surface $X$ and a reduced anti-canonical divisor $D$, Shokurov’s criterion asserts that if the inequality $n(D) \geq \hat{\rho}(X) + 2$ holds for the number $n(D)$ of irreducible components of $D$ and for the Weil-Picard number $\hat{\rho}(X)$, then $X$ is a toric surface and $D$ is a boundary divisor. In this talk, I will discuss the structure of $(X, D)$ which satisfies the equality $n(D) = \hat{\rho}(X) + 1$.

14:50-15:50

Osamu Fujino
Log pluricanonical representations and the abundance conjecture

Abstract. We explain the finiteness of log pluricanonical representations for projective log canonical pairs with semi-ample log canonical divisor. As an application, we can prove that the log canonical divisor of a projective semi log canonical pair is semi-ample if and only if the log canonical divisor of its normalization is semi-ample. We also discuss several other applications. This is a joint work with Yoshinori Gongyo.

Projective varieties of dimension $n$ admitting the action of a free abelian group of rank $n-1$

Abstract. Let $X$ be a normal projective variety of dimension $n > 2$ admitting the action of the group $G := \mathbb{Z}^{n-1}$ (the free abelian group of rank $n-1$) such that every non-trivial element of $G$ is of positive entropy (i.e., its action on the Neron Severi group is not quasi-unipotent). Consider the statements:

1. $X$ is not rationally connected.
2. $X$ is $G$-equivariant birational to the quotient of a complex torus.
4. the Kodaira dimension $\kappa(X)$ is non-negative.
5. $X$ is not uniruled.

We prove that (1) implies (2); (2) and (3) are equivalent. For applications, we use the known facts: (4) implies (5), and (5) implies (1).

Unipotent group actions on projective varieties

Abstract. A theory of unipotent group actions on affine varieties, e.g., $G_a$-actions, can be carried over to projective varieties via the stratification by an effective ample divisor and its iterated intersections. We then have to consider a stratified vector field on a projective variety instead of a locally nilpotent derivation on the coordinate ring of an affine variety. We thereby exploit some new topological structure of Fano threefolds of rank one and index larger than one. This is a joint work with R.V. Gurjar and K. Masuda.

A Gromov Winkelmann type theorem for flexible varieties

Abstract. An affine variety $X$ over $\mathbb{C}$ of dimension $\geq 2$ is called flexible if its special automorphism group $\text{SAut}(X)$ acts transitively on the smooth locus $X_{\text{reg}}$. Here the special automorphism group $\text{SAut}(X)$ is the subgroup of the automorphism group $\text{Aut}(X)$ generated by all one-parameter unipotent subgroups. Given a normal, flexible, affine variety $X$ and a closed subvariety $Y$ in $X$ of codimension at least 2, we show that the pointwise stabilizer subgroup of $Y$ in the group $\text{SAut}(X)$ acts infinitely transitively on the complement $X \setminus Y$, that is, $m$-transitively for any $m \geq 1$. More generally we show such a result for any quasi-affine variety $X$ and codimension $\geq 2$ subset $Y$ of $X$.

In the particular case of the affine space $X = \mathbb{A}^n$, $n \geq 2$, this yields a Theorem of Gromov and Winkelmann.

Alexander Perepechko

Flexibility of affine varieties covered by toric charts

Abstract. The talk is based on the joint work with Hendrik Süß and Mateusz Michałek. We study two families of affine varieties covered by toric open charts and prove their flexibility.

Let $X$ be an affine algebraic variety of dimension $\geq 2$ defined over an algebraically closed field $K$ of characteristic zero, and let $\mathrm{SAut} X$ be the subgroup of automorphism group $\mathrm{Aut} X$ that is generated by the 1-parameter unipotent subgroups, i.e. actions of the additive group $G_a = G_a(K)$.

A variety $X$ is called flexible if the tangent space to $X$ at an arbitrary regular point $x \in X$ is generated by tangent vectors to orbits of $G_a$-actions. This is equivalent to the infinite transitivity of the action of $\mathrm{SAut} X$ on the regular locus $X_{\text{reg}} \subset X$, see [1].

Previously described classes of flexible varieties include: affine cones over flag varieties, non-degenerate toric varieties of dimension $\geq 2$, and suspensions over flexible varieties [2]; affine cones over del Pezzo surfaces of degree $\geq 4$ [5]; universal torsors over $A$-covered varieties [3].

We will prove flexibility of the following families of varieties:

1. affine cones over secant varieties of Veronese–Segre varieties;
2. total coordinate spaces of smooth projective $T$-varieties of complexity $1$.

We use the construction from [4] that provides a certain correspondence between open cylindric subsets on a projective variety $Y$ and regular $G_a$-actions on the affine cone over $Y$.

Birational tentative to produce a counter-example for Abhyankar-Sathaye embedding problem of dimension three

Abstract. The geometry on del Pezzo surfaces plays often important roles for not only birational geometry but also affine geometry. In this talk, we will talk of some birational tentative to produce a counter-example for Abhyankar-Sathaye embedding problem in dimension three by make use of smooth del Pezzo surfaces $S$ of degree one with log-canonical threshold $\text{lct}(S) = 5/6$, in other words, $S$ with an anti-canonical rational cuspidal curve, say $C \in |-K_S|$. More precisely, it is well known that a del Pezzo surface $S$ of degree $(-K_S)^2 = 1$ is embedded in the weighted projective space $\mathbb{P}(1, 1, 2, 3)$ as a hypersurface of degree 6, so that we take a hyperplane $H \in |\mathcal{O}_{\mathbb{P}(1, 1, 2, 3)}(1)|$ in such a way that $S \circ H = C$ scheme-theoretically. Then our main interest consists in a detailed observation of the pencil $\Lambda$ spanned by $S$ and $6H$, namely, we perform in an explicit manner the process to resolve $B \circ \Lambda = C$ and then execute minimal model program (mmp) relative to the morphism defined by a resolved pencil. In fact, the output of a relative (mmp) is either a del Pezzo fibration of degree one $(\text{dP})_1$ or a Mori conic bundle (MCB). In consideration of the results due to Grinenko and Pukhlikov concerning birational rigidity on certain del Pezzo fibrations of low degree, it seems to be reasonable to expect, to some extent, that the output is actually an (MCB). Nevertheless, we give an example of $S$ in which the corresponding output is $(\text{dP})_1$. Further, we see that provided we reach an (MCB) by choosing $S$ suitably, we can construct a counter-example of Abhyankar-Sathaye embedding problem in dimension three. (However, we do not know so far any example of $S$ such that the corresponding output of a relative (mmp) ends with an (MCB).)

Amalgamations and Automorphism Groups

Abstract. We review some facts about automorphism groups over polynomial rings. It is shown that the tame subgroup of the group of polynomials automorphisms of affine 3-space can be realized as the product of three subgroups, amalgamated along pairwise intersections, in a manner that generalizes the well-known amalgamated free product structure in dimension 2. The result follows from the defining relations for the tame subgroup given by U. U. Umirbaev.

Shigeru Kuroda

Lnd-automorphisms and the Linearization Problem

Abstract. Let \( R \) be a \( \mathbb{Q} \)-domain, and \( \delta \) a nonzero locally nilpotent derivation of \( R \). Then, an automorphism \( \exp \delta \) of the ring \( R \) is defined by

\[
(\exp \delta)(a) = \sum_{l=0}^{\infty} \frac{\delta^l(a)}{l!} \text{ for each } a \in R.
\]

Note that \( R^\delta := \{ a \in R \mid \delta(a) = 0 \} \) is a subring of \( R \), and \( \exp \delta \) belongs to the automorphism group \( \operatorname{Aut}(R/R^\delta) \) of the \( R^\delta \)-algebra \( R \). Let \( \operatorname{LND}(R/R^\delta) \) be the set of locally nilpotent \( R^\delta \)-derivations of \( R \). Then, for each \( D \in \operatorname{LND}(R/R^\delta) \), we have \( R^D \supset R^\delta \), and so \( \exp D \in \operatorname{Aut}(R/R^D) \subset \operatorname{Aut}(R/R^\delta) \). Hence,

\[
E_\delta := \{ \exp D \mid D \in \operatorname{LND}(R/R^\delta) \}
\]

is a subset of \( \operatorname{Aut}(R/R^\delta) \). In fact, \( E_\delta \) forms a normal subgroup of \( \operatorname{Aut}(R/R^\delta) \). In this talk, we study the quotient group

\[
\operatorname{Aut}(R/R^\delta)/E_\delta.
\]

For example, let \( k \) be a field of characteristic zero, and \( R = k[x_1, x_2, x_3] \) the polynomial ring in three variables over \( k \). Then,

\[
\delta = x_2 \frac{\partial}{\partial x_1} - 2x_3 \frac{\partial}{\partial x_2}
\]

is a locally nilpotent derivation of \( R \) with \( R^\delta = k[x_1 x_3 + x_2^2, x_3] \). It is well known that the famous automorphism given by Nagata is an element of \( E_\delta \) for this \( \delta \). The \( k \)-automorphism \( \phi \) of \( R \) defined by \( \phi(x_2) = -x_2 \) and \( \phi(x_i) = x_i \) for \( i = 1, 3 \) belongs to \( \operatorname{Aut}(R/R^\delta) - E_\delta \). In this case, \( \operatorname{Aut}(R/R^\delta)/E_\delta \) is a cyclic group of order two generated the image of \( \phi \).

A special case of Kambayashi’s Linearization Problem asks whether every finite-order \( k \)-automorphism of the polynomial ring \( k[x_1, \ldots, x_n] \) with \( k = k \) is linearizable. When \( R = k[x_1, \ldots, x_n] \), the study of \( \operatorname{Aut}(R/R^\delta)/E_\delta \) is closely related to the study of the Linearization Problem. Actually, every element of \( \operatorname{Aut}(R/R^\delta) - E_\delta \) has finite order unless \( R \) is a polynomial ring in one variable over \( R^\delta \). We discuss when \( E_\delta \) equals \( \operatorname{Aut}(R/R^\delta) \) from the view point of linearizability of elements of \( \operatorname{Aut}(R/R^\delta) - E_\delta \) and triangularizability of \( \delta \). We also announce some recent results on the Linearization Problem.

**Group of birational transformations generated by the standard and linear transformations**

**Abstract.** The famous Noether-Castelnuovo theorem says that the group of birational transformations of the plane is generated by linear automorphisms and the standard quadratic transformation, when the field is algebraically closed. In dimension higher or when working over non-closed field, the result fails, and the only reason for a map not being generated by these simple maps is that some non-rational hypersurface is contracted. I will describe other criteria, which are geometric but can also be viewed algebraically.

**Homogeneous locally nilpotent derivations of \( k[x, y, z] \)**

**Abstract.** Let \( B \) be a polynomial ring in 3 variables over an algebraically closed field \( k \) of characteristic zero. If \( g \) is any grading of \( B \), define

\[
\text{LND}(B, g) = \text{set of locally nilpotent derivations } D : B \to B \text{ that are homogeneous with respect to } g.
\]

By a *positive grading* of \( B \), we mean an \( \mathbb{N} \)-grading \( B = \bigoplus_{n \in \mathbb{N}} B_n \) satisfying \( B_0 = k \). The talk will present recent progress in:

**Problem.** Describe \( \text{LND}(B, g) \) for each positive grading \( g \) of \( B \).

Open algebraic surfaces of non-negative logarithmic Kodaira dimension

ABSTRACT. We discuss open algebraic surfaces of non-negative logarithmic Kodaira dimension over an algebraically closed field of arbitrary characteristic. After recalling structure theorems for open algebraic surfaces, we give some results on logarithmic plurigenera of open algebraic surfaces of non-negative logarithmic Kodaira dimension. In particular, we show that, for a smooth irrational open algebraic surface $S$, $\pi(S) \geq 0$ if and only if $P_{12}(S) > 0$. We also give some results on open algebraic surfaces of $K = 0$.
